Coarse topology, enlargeability, and essentialness

SOCIÉTÉ MATHÉMATIQUE DE FRANCE

COARSE TOPOLOGY, ENLARGEABILITY, AND ESSENTIALNESS

BY BERNHARD HANKE, DIETER KOTSCHICK, JOHN ROE
AND THOMAS SCHICK

ABSTRACT. – Using methods from coarse topology we show that fundamental classes of closed enlargeable manifolds map non-trivially both to the rational homology of their fundamental groups and to the K -theory of the corresponding reduced C^* -algebras. Our proofs do not depend on the Baum–Connes conjecture and provide independent confirmation for specific predictions derived from this conjecture.

RÉSUMÉ. – En utilisant des méthodes de topologie à grande échelle, on prouve que les classes fondamentales des variétés agrandissables ne s’annulent pas, ni dans l’homologie rationnelle de leurs groupes fondamentaux, ni dans la K -théorie des C^* -algèbres réduites correspondantes. Nos résultats ne dépendent pas de la conjecture de Baum–Connes, et confirment de façon indépendante certaines conséquences de cette conjecture.

1. Introduction and statement of results

In this paper we use methods from coarse topology to prove certain homological properties of enlargeable manifolds. The defining property of this class of manifolds is that they admit covering spaces that are uniformly large in all directions. The intuitive geometric meaning of enlargeability is naturally captured by concepts of coarse topology, in particular by the notion of macroscopic largeness. We proceed by showing that enlargeability implies macroscopic largeness, which in turn implies homological statements in classical, rather than coarse, algebraic topology.

Using completely different methods, related results were previously proved in [15, 16]. We shall discuss the comparison between the two approaches later in this introduction, after setting up some of the terminology to be used. Suffice it to say for now that our results here, unlike those of [15, 16], are relevant to the Baum–Connes conjecture for the reduced group C^* -algebra, in that we verify specific predictions derived from this conjecture.

Enlargeability. – Several versions of the notion of enlargeability or hypersphericity were introduced by Gromov and Lawson in [13, 14]. Here is the basic definition:

DEFINITION 1.1. – A closed oriented manifold M of dimension n is called *enlargeable* if for every $\epsilon > 0$ there is a covering space $M_\epsilon \longrightarrow M$ that admits an ϵ -contracting map

$$f_\epsilon : M_\epsilon \longrightarrow (S^n, g_{can})$$

to the n -sphere with its canonical metric, which is constant outside a compact set, and is of nonzero degree.

Here all covering spaces M_ϵ are given the pullback metrics induced by an arbitrary metric on M . The choice of metric on M matters only in that it has to be independent of ϵ .

A variation on this definition is obtained by restricting the kind of covering space allowed for M_ϵ . We shall call M *universally enlargeable* if it is enlargeable and for all ϵ the covering M_ϵ can be taken to be the universal covering $\widetilde{M} \longrightarrow M$. We shall call M *compactly enlargeable* if it is enlargeable and all M_ϵ can be taken to be compact, equivalently to be finite-sheeted coverings.

Essentialness. – Recall that Gromov [9] called a closed oriented manifold M *essential* if its fundamental class maps non-trivially to the rational homology of $B\pi_1(M)$ under the classifying map of its universal cover. It is natural to extend this definition to more general situations. For any homology theory E , we say that an E -oriented manifold M is *E -essential* if its orientation class maps non-trivially to $E_*(B\pi_1(M))$ under the classifying map of the universal covering.

In the context of coarse topology, one replaces the usual orientation class of M by the orientation class of the universal covering \widetilde{M} in the coarse homology $HX_*(\widetilde{M})$, see Section 2 below. Passing to the coarse homology of the universal covering is a procedure not unlike passing from M to the classifying space of its fundamental group, and the coarse fundamental class $[\widetilde{M}]_X$ may well vanish. We shall say that a manifold M (or its universal covering) is *macroscopically large* if it is essential for coarse homology, i. e. if $[\widetilde{M}]_X \neq 0 \in HX_*(\widetilde{M})$. In fact, Gromov suggested various versions of macroscopic largeness in [10, 11, 12], and this definition, taken from [8], is just one particular way of formalizing the concept.

We can now state our first main result.

THEOREM 1.2. – (1) *Universally enlargeable manifolds are macroscopically large.*
 (2) *Macroscopically large manifolds are essential in rational homology.*

There are results by Dranishnikov [6] addressing the converse to the first part of this theorem. He has shown that other notions of macroscopic largeness sometimes imply versions of enlargeability.

Combining the two implications in Theorem 1.2, we obtain:

COROLLARY 1.3. – *Universally enlargeable manifolds are essential in rational homology.*

FIGURE 1. The connected balloon space B^n

That compactly enlargeable manifolds are essential was conjectured by Burghelea [26, Problem 11.1] quite some time ago and was proved fairly recently by Hanke and Schick [15], using index theory and the K -theory of C^* -algebras. One of the motivations for the present paper was the wish to give a direct and elementary proof of such a result, which does not use index theory and K -theory. After we achieved this goal by finding the proof of Theorem 1.2 given in Section 3 below, it turned out that the sophisticated methods of [15] can also be adapted to the consideration of infinite covers [16].

While the ideas involved in our proof of Theorem 1.2 are indeed geometric and elementary, they do fit naturally into the framework of coarse homology, which we recall in Section 2 following the books [22, 24]. Our argument makes essential use of the coarse space

$$B^n = [0, \infty) \cup_{\{1,2,3,\dots\}} (\cup_i S^n(i)) .$$

This balloon space, sketched in Figure 1, is a coarse analogue of the one-point union. It is defined using a collection of n -spheres of increasing radii $i = 1, 2, 3, \dots$, with the sphere of radius i attached to the point $i \in [0, \infty)$ at the south pole of S^n , and is equipped with the path metric.

The enlargeability assumption will be used to construct a coarse map

$$\widetilde{M} \longrightarrow B^n$$

that sends the coarse fundamental class of \widetilde{M} to a nonzero class in the coarse homology of B^n (see Proposition 3.1). After this has been established, the proof of Theorem 1.2 can be completed quite easily.

Applications to the Baum–Connes map. – After giving the proof of Theorem 1.2, we proceed to use coarse topology to study the relation between enlargeability and the Baum–Connes assembly map in complex K -theory. This will lead us to some novel results on the Baum–Connes map that are interesting both in their own right and because of what they say about the relationship between various obstructions to the existence of positive scalar curvature metrics.

To formulate our results we make the following definition.

DEFINITION 1.4. – A closed K -theory oriented manifold M is *Baum–Connes essential* if the image of its K -theoretic fundamental class under the composite map

$$K_*(M) \xrightarrow{c_*} K_*(B\pi_1(M)) \xrightarrow{\mu} K_*(C_{\text{red}}^*\pi_1(M))$$

is non-zero. Here, $c: M \longrightarrow B\pi_1(M)$ classifies the universal covering of M , and μ is the Baum–Connes assembly map.

In contrast to [15, 16], we will work with the *reduced* group C^* -algebra throughout the present paper. We use the letter K for the compactly supported complex K -homology defined by the K -theory spectrum. This is different from the convention in [22], where K_* denotes the analytically defined, hence locally finite K -homology.

Recall that a smooth manifold M is orientable with respect to K -theory if and only if its tangent bundle admits a Spin^c -structure. If M is compact, then any choice of Spin^c -structure determines a fundamental class $[M]$ in K -homology given by the corresponding Dirac operator, cf. [18, Chapter 11]. The image

$$\alpha(M) = \mu \circ c_*([M]) \in K_*(C_{\text{red}}^*\pi_1(M))$$

is given by the index of the Spin^c Dirac operator on M twisted by the flat Hilbert module bundle

$$\widetilde{M} \times_{\pi_1(M)} C_{\text{red}}^*\pi_1(M) \longrightarrow M$$

on M , as can be seen for example by a description of the Baum–Connes assembly map via Kasparov’s KK -theory; cf. [3].

If a Spin^c -structure on M is induced by a spin structure, then the above construction can also be performed in real K -theory, leading to $\alpha_{\mathbb{R}}(M) \in KO_*(C_{\text{red}}^*\pi_1(M))$. In this case $\alpha(M)$ is the image of $\alpha_{\mathbb{R}}(M)$ under complexification. The Weitzenböck formula for the spin Dirac operator implies via the Lichnerowicz argument that if M endowed with the fundamental class of a spin structure is Baum–Connes essential, then it does not admit a metric of positive scalar curvature. The Gromov–Lawson–Rosenberg conjecture predicts that the vanishing of $\alpha_{\mathbb{R}}(M)$ on a closed spin manifold M is not only necessary, but also sufficient for the existence of a positive scalar curvature metric on M . Although this conjecture does not hold in general [7, 25], it is expected that $\alpha_{\mathbb{R}}(M)$ captures all index-theoretic obstructions to the existence of a positive scalar curvature metric on M . This expectation is based in part on the relationship between the Gromov–Lawson–Rosenberg conjecture and the Baum–Connes conjecture.

Recall [2] that the Baum–Connes conjecture claims that for any discrete group Γ , the assembly map

$$K_*^\Gamma(\underline{E}\Gamma) \longrightarrow K_*(C_{\text{red}}^*\Gamma)$$

is an isomorphism, where $\underline{E}\Gamma$ is the universal space for proper Γ -actions, and K_* denotes K -homology with compact supports. The assembly map

$$\mu: K_*(B\Gamma) \longrightarrow K_*(C_{\text{red}}^*\Gamma)$$

considered above factors as

$$K_*(B\Gamma) \xrightarrow{\cong} K_*^\Gamma(E\Gamma) \xrightarrow{\gamma} K_*^\Gamma(\underline{E}\Gamma) \longrightarrow K_*(C_{\text{red}}^*\Gamma),$$

where the first map is the canonical isomorphism between the equivariant K -theory of the free Γ -space $E\Gamma$ and the K -theory of the quotient $B\Gamma$ and γ is induced by the canonical map $E\Gamma \rightarrow \underline{E}\Gamma$. Stolz [27] has proved that if M is spin and the Baum–Connes conjecture holds for the group $\pi_1(M)$, then the vanishing of $\alpha_{\mathbb{R}}(M)$ is sufficient for M to stably admit a metric of positive scalar curvature. Here “stably” means that one allows the replacement of M by its product with many copies of a Bott manifold B , which is any simply connected

8-dimensional spin manifold with $\hat{A}(B) = 1$. This result can be regarded as an instance of the universal nature of the index obstruction $\alpha_{\mathbb{R}}(M)$.

It can be shown that the map γ is rationally injective. Hence, if the Baum–Connes conjecture is true for $\pi_1(M)$, then M is Baum–Connes essential if, and clearly only if, it is K -theory essential (for K -theory with rational coefficients). In this direction, we shall prove the following unconditional result. We do not assume the Baum–Connes conjecture, which has not yet been verified in full generality and is actually expected to fail for some wild groups.

THEOREM 1.5. – *Every closed universally enlargeable Spin^c -manifold is Baum–Connes essential.*

In Section 4 we shall discuss the coarse version of the Baum–Connes conjecture. It will become clear that if this were known to be true, then Theorem 1.5 would follow from the first part of Theorem 1.2. However, our proof of Theorem 1.5 will bypass this issue.

In the spin case, Theorem 1.5 essentially shows that the Gromov–Lawson obstruction [13, 14] to the existence of positive scalar curvature provided by enlargeability is subsumed by the index-theoretic obstruction $\alpha_{\mathbb{R}}(M)$, and even by $\alpha(M)$. Hanke and Schick previously proved this for the corresponding invariant in the K -theory of the maximal C^* -algebra of $\pi_1(M)$; see [15, Theorem 1.2] and [16]. Our result here neither implies nor is it implied by that of [15, 16]. On the one hand, the canonical map

$$K_*(C_{\max}^*\pi_1(M)) \longrightarrow K_*(C_{\text{red}}^*\pi_1(M))$$

is not always injective, so that our conclusion here is stronger than the one in [15, 16]. On the other hand, we also use a stronger assumption, enlargeability, which implies the assumption of area-enlargeability used in [15, 16]. (For area-enlargeability, the ϵ -contracting property of f_ϵ is required not for lengths, but only for two-dimensional areas.)

Having shown that the enlargeability obstruction to the existence of positive scalar curvature metrics is indeed subsumed by the universal index obstruction $\alpha_{\mathbb{R}}(M)$, we want to go further and also show this for the obstruction derived from \hat{A} -enlargeability in the sense of Gromov and Lawson [13, 14]. We slightly generalize this concept by considering the following amalgamation of enlargeability and K -theoretic essentialness:

DEFINITION 1.6. – A closed Spin^c -manifold M is called *K -theory enlargeable* if there is an $n \in \mathbb{N}$ such that for every $\epsilon > 0$ there is a covering space $M_\epsilon \longrightarrow M$ that admits an ϵ -contracting map

$$f_\epsilon : M_\epsilon \longrightarrow (S^n, g_{\text{can}})$$

to the n -sphere with its canonical metric, which maps the complement of a compact set to the base point (equal to the south pole, say) $S \in S^n$, and sends the K -theoretic orientation class to a non-trivial element of $K_*(S^n, S)$.

When n is the dimension of M , this definition reduces to Definition 1.1. We shall prove the following generalization of Theorem 1.5:

THEOREM 1.7. – *Every K -theory enlargeable Spin^c -manifold is Baum–Connes essential.*

Note that in addition to considering K -theory enlargeability, we now also allow arbitrary covering spaces in the definition of enlargeability, whereas in Theorem 1.5 we only used the universal covering.

If the Spin^c structure under consideration is induced by a spin structure, then the image of the K -theoretic fundamental class under f_ϵ is given by the \hat{A} -genus of a regular fiber, and K -theory enlargeability reduces to \hat{A} -enlargeability in the sense of Gromov and Lawson. The conclusion of Theorem 1.7 means that $\alpha(M)$ does not vanish. *A fortiori* the real index $\alpha_{\mathbb{R}}(M)$ does not vanish either, so that the obstruction to the existence of a positive scalar curvature metric on M provided by \hat{A} -enlargeability is completely subsumed by $\alpha_{\mathbb{R}}(M)$.

Just like Theorem 1.5, we prove Theorem 1.7 unconditionally, without assuming any unproved version of the Baum–Connes conjecture. However, if the Baum–Connes conjecture does hold for $\pi_1(M)$, then the special case of this theorem for Spin^c -structures induced by spin structures can be derived from the result of Stolz mentioned above, because \hat{A} -enlargeability is preserved by stabilisation with the Bott manifold.

Although Theorem 1.5 is a special case of Theorem 1.7, we shall first give a proof of this special case using the same ideas as in the proof of Theorem 1.2. Then, in order to prove Theorem 1.7 in full generality, we will face serious additional complications explained in Section 5 below. The more straightforward proof we give for the special case of Theorem 1.5 does have another advantage in addition to its simplicity, which is that it allows us to derive the following:

COROLLARY 1.8. – *If M is universally enlargeable and its universal covering \widetilde{M} is spin, then \widetilde{M} does not admit a metric with uniformly positive scalar curvature which is quasi-isometric to a pullback metric from M via the identity.*

In the more general situation considered in Theorem 1.7, the corresponding statement is not true. In fact, Block and Weinberger [4] give examples of spin manifolds M which are \hat{A} -enlargeable (with $n = 0$), but whose universal coverings do admit positive scalar curvature metrics that are quasi-isometric to pullback metrics from M . Corollary 1.8 shows in particular that examples of the kind considered in [4] can never be universally enlargeable.

Acknowledgements. – D. Kotschick would like to thank S. Weinberger, who in conversations in 2004 suggested detecting essentialness of enlargeable manifolds by mapping to (a coarse analogue of) a one-point union of spheres. B. Hanke, D. Kotschick and T. Schick are members of the DFG Priority Program in Global Differential Geometry.

2. Coarse homology

In this section we recall a few salient features of coarse homology, which we need for the proof of Theorem 1.2. Our reference is [22], see also [24].

Let M be a topological space. Its locally finite homology $H_*^{lf}(M; \mathbb{Q})$ is the homology of the chain complex $(C_*^{lf}(M), \partial)$, where $C_i^{lf}(M)$ is the abelian group of infinite rational linear combinations

$$\sum_{\sigma} \alpha_{\sigma} \cdot \sigma$$

of singular i -simplices $\sigma: \Delta^i \rightarrow M$ with the property that each compact set in M is met by only finitely many simplices.

This locally finite homology theory is a functor on the category of topological spaces and proper continuous maps.

Now let M be a proper metric space. The coarse homology $HX_*(M; \mathbb{Q})$ is defined as follows. Let \mathfrak{U}_i be a coarsening sequence of covers of M in the sense of [22, p. 15]. We then set

$$HX_*(M) := \lim_{\rightarrow_i} H_*^{lf}(|\mathfrak{U}_i|),$$

where $|\mathfrak{U}_i|$ is the geometric realization of the nerve of \mathfrak{U}_i . Coarse homology is functorial for coarse maps, which in the case of length spaces are precisely the proper maps which are large scale Lipschitz, see the definitions in [22, p. 9].

Lastly, let M^n be a closed oriented manifold. Fix a metric and a triangulation of M . The sum of all the lifts (with induced orientations) of the n -simplices in M with respect to the projection $\widetilde{M} \rightarrow M$ defines the locally finite fundamental class

$$[\widetilde{M}]_{lf} \in H_n^{lf}(\widetilde{M}).$$

Note that there is a canonical map

$$H_*^{lf}(\widetilde{M}) \rightarrow HX_*(\widetilde{M}).$$

Indeed, let d be the maximal diameter of simplices in M . Then the set of all open balls of radius $2d$ around each vertex in \widetilde{M} defines an open cover \mathfrak{U} of \widetilde{M} which we can use as a particular cover in the coarsening sequence (\mathfrak{U}_i) in the definition of coarse homology. It follows from the definition of the geometric realization $|\mathfrak{U}|$ that the simplicial complex \widetilde{M} has a natural simplicial map to $|\mathfrak{U}|$ and the above map is simply the composition

$$H_*^{lf}(\widetilde{M}) \rightarrow H_*^{lf}(|\mathfrak{U}|) \rightarrow HX_*(\widetilde{M}).$$

The coarse fundamental class $[\widetilde{M}]_X$ of \widetilde{M} is defined as the image of $[\widetilde{M}]_{lf}$ under this map.

This construction actually applies not just to universal covers of closed manifolds, but to all complete manifolds with bounded geometry. Using it, we now define macroscopic largeness.

DEFINITION 2.1 ([8]). – A complete oriented Riemannian manifold N with bounded geometry is called *macroscopically large* if

$$[N]_X \neq 0 \in HX_n(N),$$

where HX_* denotes the coarse homology.

As an example for the calculation of coarse homology, fix a natural number n and consider the balloon space

$$B^n = [0, \infty) \cup_{\{1,2,3,\dots\}} (\cup_i S^n(i)).$$

PROPOSITION 2.2. – The coarse homology of B^n with \mathbb{Q} -coefficients in degree n is given by

$$HX_n(B^n) \cong \left(\prod_{i=1}^{\infty} \mathbb{Q} \right) / \left(\bigoplus_{i=1}^{\infty} \mathbb{Q} \right).$$

Proof. – For $1 \leq l < \infty$, let

$$B_{\geq l}^n \subset B^n$$

be the subspace defined by removing the first l spheres in B^n . We obtain a directed system

$$B^n = B_{\geq 1}^n \rightarrow B_{\geq 2}^n \rightarrow B_{\geq 3}^n \rightarrow \dots$$

where each map

$$B_{\geq l}^n \rightarrow B_{\geq (l+1)}^n$$

collapses the l^{th} sphere onto the point $l \in [0, \infty)$. Then (by use of an appropriate coarsening sequence for B^n), $HX_n(B^n)$ can be calculated as

$$\lim_{\rightarrow l} H_n^{lf}(B_{\geq l}^n) \cong \lim_{\rightarrow l} \left(\prod_{i=1}^{\infty} \mathbb{Q} \right) / \left(\bigoplus_{i=1}^l \mathbb{Q} \right) = \left(\prod_{i=1}^{\infty} \mathbb{Q} \right) / \left(\bigoplus_{i=1}^{\infty} \mathbb{Q} \right). \quad \square$$

3. Proof of Theorem 1.2

The first implication in Theorem 1.2 is a consequence of the following:

PROPOSITION 3.1. – *Let M be a closed oriented n -dimensional manifold which is univ-
ersally enlargeable. Then there is a coarse map*

$$\phi: \widetilde{M} \rightarrow B^n$$

such that for each $i \in \mathbb{N}$ the composition

$$\widetilde{M} \xrightarrow{\phi} B^n \rightarrow S^n(i)$$

has degree $d_i \neq 0$. Furthermore,

$$\phi_*([\widetilde{M}]_X) = (d_1, d_2, \dots) \in \left(\prod_{i=1}^{\infty} \mathbb{Q} \right) / \left(\bigoplus_{i=1}^{\infty} \mathbb{Q} \right) \cong HX_n(B^n).$$

In particular, \widetilde{M} is macroscopically large.

Proof. – Pick a Riemannian metric g on M . We construct a cover of \widetilde{M} by a sequence of compact balls

$$B_1 \subset B_2 \subset B_3 \subset \dots \subset \widetilde{M}$$

as well as a sequence of 1-contracting maps

$$f_i: \widetilde{M} \rightarrow S^n(i) \subset B^n, i = 1, 2, 3, \dots$$

as follows. Set $B_0 := \emptyset$ and assume that B_i has been constructed. Because M is enlargeable, there is a 1-contracting map

$$f_{i+1}: (\widetilde{M}, \widetilde{g}) \rightarrow S^n(i+1)$$

which is constant (mapping to the basepoint in S^n) outside a compact subset $K_{i+1} \subset \widetilde{M}$ and of non-zero degree d_{i+1} . By precomposing f_{i+1} with a deck transformation of \widetilde{M} if necessary, we can assume that

$$\text{dist}(B_i, K_{i+1}) \geq 1.$$

For $i = 0$, this condition is empty. Now for B_{i+1} we choose a closed ball containing $K_{i+1} \cup B_i$ and such that $\text{dist}(\widetilde{M} \setminus B_{i+1}, B_i) \geq 1$. Then we define

$$\phi(x) = \begin{cases} f_{i+1}(x), & \text{if } x \in K_{i+1}, \\ i + \text{dist}(x, B_i), & \text{if } 0 < \text{dist}(x, B_i) \leq 1, \\ i + 1, & \text{if } x \in B_{i+1} \setminus K_{i+1} \text{ and } \text{dist}(x, B_i) \geq 1. \end{cases}$$

The map ϕ is proper by definition, and it is large scale Lipschitz also by definition and because each f_i is 1-contracting. Thus ϕ is indeed a coarse map.

The claim about the image of the fundamental class follows from the calculation of $HX_n(B^n)$ in Proposition 2.2. □

This proof makes clear why we use the space B^n , rather than the one-point union of the spheres— using the latter would not give us a proper map.

The following is the contraposition of the second part of Theorem 1.2.

PROPOSITION 3.2. – *If M is not essential, then \widetilde{M} is not macroscopically large.*

Proof. – Assume that M is not essential. Then there is a finite subcomplex $S \subset B\pi_1(M)$ such that $c(M) \subset S$, the inclusion $S \subset B\pi_1(M)$ induces an isomorphism on fundamental groups, and $c_*([M]) = 0 \in H_n(S; \mathbb{Q})$. Note that we use ordinary homology. Hence, if a chain in $B\pi_1(M)$ is a boundary, it is also a boundary in some finite subcomplex of $B\pi_1(M)$.

We may assume without loss of generality that M is a finite subcomplex of S and $c: M \rightarrow S$ is the inclusion. We choose a metric on S . The induced inclusion

$$\widetilde{M} \xrightarrow{\widetilde{c}} \widetilde{S}$$

is then a coarse equivalence.

We claim that the induced map

$$HX_*(\widetilde{M}) \xrightarrow{\widetilde{c}_*} HX_*(\widetilde{S})$$

sends $[\widetilde{M}]_X$ to zero. This is true for the following reason. Let the simplicial chain $C_M \in C_n(M; \mathbb{Q})$ represent the fundamental class of M , and let $b \in C_{n+1}(S; \mathbb{Q})$ be a simplicial chain with $\partial b = C_M$. This exists by the choice of S . As above we find an open cover \mathcal{U} of \widetilde{S} by open balls with radius $2d$ (where d is the maximal diameter of the simplices in S) so that \widetilde{S} is a subcomplex of $|\mathcal{U}|$. In particular, the chain b induces a chain $\widetilde{b} \in C_{n+1}(|\mathcal{U}|)$ (by lifting b to $\widetilde{S} \subset |\mathcal{U}|$) and the boundary of \widetilde{b} is equal to $C_{\widetilde{M}}$, where $C_{\widetilde{M}}$ is the lift of C_M . Hence, we can indeed conclude that the homology class of $C_{\widetilde{M}}$ vanishes in $HX_n(\widetilde{S})$.

The inclusion \widetilde{c} is a coarse equivalence and so $[\widetilde{M}]_X \in HX_n(\widetilde{M})$ vanishes. Therefore \widetilde{M} is not macroscopically large. □

4. Proof of Theorem 1.5

In this section we use the ideas from the proof of Theorem 1.2 to prove Theorem 1.5 and Corollary 1.8, using K -homology instead of ordinary homology.

The coarse Baum-Connes conjecture, see [22, Conjecture 8.2.], predicts that for a metric space M of bounded geometry, the coarse assembly map

$$\mu_\infty : KX_*(M) \longrightarrow K_*(C^*(M)),$$

see [22, Chapter 8], is an isomorphism. Here, $KX_*(M)$ denotes coarse homology based on locally finite complex K -homology and $C^*(M)$ is the C^* -algebra of locally compact finite propagation operators on M , see [22, Definition 3.4.].

At this point it is useful to remark that locally finite K -homology can be defined in two ways. On the one hand, the operator-theoretic description of K -homology, which is used in [22] for defining the assembly map μ_∞ , leads directly to a locally finite theory. On the other hand, the paper [19] associates to any homology theory E a Steenrod homology theory E_*^{st} defined on compact metric pairs. One then defines the locally finite E -homology $E_*^{lf}(M)$ of a locally compact metric space M as the Steenrod E -homology of the compact pair $(M \cup \{\infty\}, \{\infty\})$, where $M \cup \{\infty\}$ is the one-point compactification of M . If M is a countable and locally finite CW complex and E is ordinary homology, then this definition coincides with our previous definition from Section 2, see [21, Theorem 1]. In the case of K -homology, the two descriptions of the locally finite theory coincide by [20].

PROPOSITION 4.1. – *The balloon spaces B^n satisfy the coarse Baum-Connes conjecture.*

This can be seen by referring to a deep result of Yu [29] saying that the coarse Baum-Connes conjecture is true for metric spaces of bounded geometry which admit uniform embeddings into separable complex Hilbert spaces. However, the spaces B^n are simple enough to check the coarse Baum-Connes conjecture by a direct calculation. This will be performed later in this paper for slightly different spaces \mathcal{B}^n , see Proposition 5.2, and can be adapted easily to the B^n .

We now start the proof of Theorem 1.5. Let M be a closed universally enlargeable Spin^c -manifold. We set $\pi = \pi_1(M)$.

The composition

$$K_*(M) \xrightarrow{c_*} K_*(B\pi) \xrightarrow{\mu} K_*(C_{\text{red}}^*\pi).$$

can alternatively be regarded as the composition

$$K_*(M) \xrightarrow{PD} K_{*+1}(D_\pi^*(\widetilde{M})/C_\pi^*(\widetilde{M})) \xrightarrow{\partial} K_*(C_\pi^*(\widetilde{M})) \cong K_*(C_{\text{red}}^*\pi).$$

Here we work with the operator-theoretic description of K -theory and the assembly map from [22, Chapter 5] using a Paschke duality map PD and a connecting homomorphism ∂ . Recall from that reference that $D^*(\widetilde{M})$ is the C^* -algebra generated by all pseudolocal finite propagation operators on \widetilde{M} and the subscript π indicates that only π -invariant pseudolocal (or locally compact) finite propagation operators are contained in the generating set.

It is therefore enough to show that the composition

$$K_*(M) \longrightarrow K_*(C_\pi^*(\widetilde{M})) \longrightarrow K_*(C^*(\widetilde{M}))$$

sends the K -theoretic fundamental class of M to a non-zero class. This composition can be factored through the transfer map

$$tr : K_*(M) = K_{*+1}(D_\pi^*(\widetilde{M})/C_\pi^*(\widetilde{M})) \longrightarrow K_{*+1}(D^*(\widetilde{M})/C^*(\widetilde{M})) = K_*^{lf}(\widetilde{M}).$$

This map simply forgets the π -action. We obtain a commutative diagram

$$(1) \quad \begin{array}{ccc} K_*(M) & \longrightarrow & K_*(C^*(\widetilde{M})) \\ tr \downarrow & & = \downarrow \\ K_*^{lf}(\widetilde{M}) & \longrightarrow & K_*(C^*(\widetilde{M})) \\ \downarrow & & = \downarrow \\ KX_*(\widetilde{M}) & \xrightarrow{\mu_\infty} & K_*(C^*(\widetilde{M})) \\ \downarrow \phi_* & & \phi_* \downarrow \\ KX_*(B^n) & \xrightarrow[\cong]{\mu_\infty} & K_*(C^*(B^n)), \end{array}$$

where ϕ_* is induced by the coarse map $\phi : \widetilde{M} \longrightarrow B^n$ defined in Section 3.

Because μ_∞ is an isomorphism for B^n by Proposition 4.1, it is enough to show that the image of the K -theoretic fundamental class $[M]_K$ of M in $KX_*(B^n)$ is non-zero. This can be done exactly as in the proof of Theorem 1.2 (1), using K -homology instead of ordinary homology. Namely, one establishes that $KX_n(B^n) \cong (\prod \mathbb{Z})/(\bigoplus \mathbb{Z})$, and that again $[M]_K$ is mapped to the sequence represented by the degrees of the $f_{1/i}$, which is by assumption non-zero in the quotient group.

This completes the proof of Theorem 1.5. To prove Corollary 1.8, notice that if the universal covering \widetilde{M} is spin, then we can start the argument with the K -theoretic orientation class of the spin structure in the group $K_*^{lf}(\widetilde{M})$ in (1), rather than starting at $K_*(M)$ and applying the transfer. Then the usual Lichnerowicz argument and the coarse invariance of $K_*(C^*(\widetilde{M}))$ imply the conclusion.

5. Coarse C^* -algebras with coefficients

5.1. Outline of the proof of Theorem 1.7. – The proof of Theorem 1.7 is based on ideas similar to those in our proofs of Theorems 1.2 and 1.5. However, the discussion of manifolds that are enlargeable with respect to arbitrary coverings requires a substantial refinement of these methods because we cannot work with the universal covering only and have to use many different coverings at once. We do this by introducing the coarse space

$$\mathcal{M} := \bigcup_{i=1,2,3,\dots} M_{1/i}$$

where $M_{1/i}$ is the covering of M with an $1/i$ -contracting map to S^n given by enlargeability, and where the distinct components are placed at distance ∞ from each other. Note that this does not mean that these components are independent from each other - for the coarse type of this space, global metric bounds (i. e. referring to all components at once) will be crucial.

FIGURE 2. The balloon space \mathcal{B}^n , with infinite whiskers attached to each sphere.

The balloon space \mathcal{B}^n considered before now has to be replaced by the disjoint union

$$\mathcal{B}^n := \bigcup_{i=1,2,3,\dots} \underline{S}^n(i),$$

where the notation \underline{S}^n means that a whisker of infinite length is attached at the south pole of S^n , see Figure 2.

In a similar fashion as in the proof of Theorem 1.2, the fact that M is \hat{A} -enlargeable leads to a coarse map

$$\mathcal{M} \longrightarrow \mathcal{B}^n$$

which maps the coarse K -theoretic fundamental class of \mathcal{M} to a nonzero class in the coarse K -homology of \mathcal{B}^n . The region outside the respective compact subset in each $M_{1/i}$ (outside of which the map to S^n is constant) is mapped to the whisker in $\underline{S}^n(i)$ in order to get a proper map.

Our strategy for proving Theorem 1.7 can now be outlined as follows. The information carried by

$$\alpha(M) \in K_*(C_{\text{red}}^* \pi_1(M))$$

will be split into two parts; one goes to the K -theory of the coarse algebra of \mathcal{M} and the other is captured by introducing a collection of coefficient C^* -algebras for this coarse algebra which is equivalent to $C_{\text{red}}^* \pi_1(M_{1/i})$ over $M_{1/i}$. The relevant element in the K -group of $C^*(\mathcal{M})$ is then sent to the K -theory of the coarse algebra of \mathcal{B}^n with coefficients in the same collection of C^* -algebras. We will analyze this class by showing that the coarse assembly map with coefficients is an isomorphism for the space \mathcal{B}^n and finally using a homological version of Atiyah's L^2 -index theorem [1].

5.2. Technical preliminaries for the proof of Theorem 1.7. – Let A be a C^* -algebra and let M be a coarse metric space.

DEFINITION 5.1. – An *adequate* M -module with coefficients in A is a Hilbert A -module H together with a left $C_0(M)$ -action, i. e. a C^* -homomorphism

$$C_0(M) \longrightarrow \mathbb{B}(H),$$

where $\mathbb{B}(H)$ is the C^* -algebra of adjointable A -module homomorphisms $H \rightarrow H$; see [3, Definition VI.13.2.1]. In addition, the module H is required to be sufficiently large in the sense of [17, Definition 4.5].

For an adequate M -module H the coarse algebra $C^*(M; A)$ is defined as the algebra generated by the locally A -compact finite propagation operators in $\mathbb{B}(H)$. Note that by [17, Proposition 5.5] this construction is functorial after composing with the K -theory functor.

We define the coarse K -homology of M with coefficients in A as

$$KX_*(M; A) := \lim_{\rightarrow_i} KK_*(C_0(|\mathcal{U}_i|); A),$$

where $(|\mathcal{U}_i|)_i$ is a coarsening sequence for M . Recall that $KK_*(C_0(M); A)$ is a locally finite theory. If M is a manifold we can start with a (fine) covering whose nerve is homeomorphic to M and will therefore obtain a canonical map $K_*^{lf}(M; A) \rightarrow KX_*(M; A)$, called a coarsening map.

In analogy with [22, Chapter 5] we have an assembly map

$$\mu : KK_*(C_0(M); A) \rightarrow K_*(C^*(M; A))$$

which factors through $KX_*(M; A)$ and defines the coarse assembly map

$$\mu_\infty : KX_*(M; A) \rightarrow K_*(C^*(M; A)),$$

compare p. 75 of [22].

As discussed in Section 4 above, the coarse Baum-Connes conjecture predicts that for a metric space M of bounded geometry, the coarse assembly map

$$\mu_\infty : KX_*(M; \mathbb{C}) \rightarrow K_*(C^*(M))$$

is an isomorphism. Here $C^*(M) = C^*(M; \mathbb{C})$ is the usual coarse algebra of locally compact finite propagation operators on M as considered before. We shall now prove a generalized version of this conjecture with coefficients for the spaces

$$\mathcal{B}^n := \bigcup_{i=1,2,3,\dots} \underline{S}^n(i)$$

introduced in Subsection 5.1. Recall that \underline{S}^n denotes an n -sphere to which a whisker of infinite length has been attached at the south pole.

PROPOSITION 5.2. – *Let A be a C^* -algebra. Then the coarse assembly map*

$$KX_*(\mathcal{B}^n; A) \xrightarrow{\mu_\infty} K_*(C^*(\mathcal{B}^n; A))$$

is an isomorphism.

This proposition plays the same role in the proof of Theorem 1.7 as did Proposition 4.1 in the proof of Theorem 1.5. The proof of Proposition 5.2 is by induction on n and uses a Mayer-Vietoris argument. Let us first collect some facts concerning Mayer-Vietoris sequences for coarse K -theory and for K -theory of coarse algebras.

1. The K -theory of coarse C^* -algebras with coefficients has a Mayer-Vietoris sequence for coarsely excisive decompositions, by [17, Corollary 9.5]. Here a decomposition $X = X_1 \cup X_2$ is *coarsely excisive* if for each $R > 0$ there is an $S > 0$ such that the intersection of the R -neighborhoods of X_1 and X_2 is contained in the S -neighborhood of $X_1 \cap X_2$.

2. The theory $KX_*(\cdot, A)$ has a Mayer–Vietoris sequence under the same assumptions as above. Recall that coarse K -homology with coefficients in A is obtained by calculating $KK(C_0(|\mathcal{U}_i|), A)$ and then passing to a limit. We now use that $X \mapsto KK(C_0(X), A)$ is a homology theory, and therefore has a Mayer–Vietoris sequence (compare [22, Section 5] for a proof if $A = \mathbb{C}$), and observe that the coarse excisiveness implies that this Mayer–Vietoris sequence is compatible with coarsening (the intersection of the nerves of the coarsening sequences for X_1 and X_2 can be chosen to give a coarsening sequence for $X_1 \cap X_2$). By passing to the direct limit, we obtain the required Mayer–Vietoris sequence in coarse K -homology. (Note that the direct limit functor is an exact functor).
3. The two Mayer–Vietoris sequences are natural with respect to the coarse assembly map.

In addition, we recall that a coarse space X is called *flasque* if there is a coarse map $t: X \rightarrow X$ which is close to the identity (in the sense of coarse geometry) and such that for each $R > 0$ there is an $S > 0$ such that $d(t^n(x), t^n(y)) < S$ for each $n \in \mathbb{N}$ and each x, y with $d(x, y) < R$, and such that for each compact set $K \subset X$ we have $t^n(K) \cap K = \emptyset$ for all sufficiently large n ; cf. [17, Section 10].

LEMMA 5.3. – [17, Proposition 10.1] *If a coarse space X is flasque, then the K -theory of its coarse C^* -algebra with coefficients vanishes.*

Proof of Proposition 5.2. – We start by describing the induction step based on the above statements.

Let $n > 0$ and consider the decomposition

$$\mathcal{B}^n = \mathcal{D}_+^n \cup \mathcal{D}_-^n,$$

where \mathcal{D}_+^n and \mathcal{D}_-^n are the unions of the left and right hemispheres in the n -spheres contained in \mathcal{B}^n , both with infinite whiskers attached at the south pole (considered as a point on the boundary of each of the two hemispheres). This decomposition is coarsely excisive. By the Mayer–Vietoris principle, it suffices to prove that the coarse assembly map is an isomorphism for \mathcal{D}_\pm^n and for their intersection. For the intersection, this is an immediate consequence of the induction hypothesis. Concerning the spaces \mathcal{D}_\pm^n , we will prove that the coarse K -theory as well as the K -theory of the associated coarse C^* -algebras (both with coefficients A) vanish. The last statement holds because the spaces \mathcal{D}_\pm^n are flasque. The required map t is constructed in the following way. We use polar coordinates to identify each hemisphere with the corresponding flat Euclidean disc of the same radius. This map has bounded distortion independent of the radii and hence gives a coarse equivalence of the spaces \mathcal{D}_\pm^n and a disjoint union (whose components have distance infinity to each other) of discs of increasing radii with whiskers on their boundaries (“lollipops”). It is therefore enough to construct the flasque map t on this disjoint union of lollipops. For each lollipop the map t moves the points one unit along a straight line towards the boundary point where the “stick” is attached and then uniformly down the stick.

Concerning the first statement, we observe that there is a coarsening sequence (\mathcal{U}_i) for \mathcal{D}_\pm^n , so that the first i components of the nerve of \mathcal{U}_i are properly homotopy equivalent to a

ray $[0, \infty)$. Because the locally finite K -homology of such a ray vanishes, we get indeed

$$KX_*(\mathcal{D}_\pm^n; A) = \varinjlim_i K_*^{lf}(|\mathcal{U}_i|; A) = 0.$$

After finishing the induction step, it remains to verify that the assembly map is an isomorphism for $n = 0$. In this case, we have a disjoint union decomposition

$$\mathcal{B}^0 = \bigcup_i (\{0\} \cup [2i, \infty))$$

where the spaces $\{0\} \cup [2i, \infty)$ carry the metric induced from $[0, \infty)$. Here, despite the fact that for different i the subspaces $\{0\} \cup [2i, \infty) \subset \mathcal{B}^0$ are at distance infinity, it is crucial that the definition of the coarse C^* -algebra requires uniform bounded propagation for its operators. For each $k \in \mathbb{N}$, we define the space

$$\mathcal{B}_k^0 = \bigcup_{i=1, \dots, k-1} [0, \infty) \cup \bigcup_{i=k, k+1, \dots} (\{0\} \cup [2i, \infty))$$

which can be identified with the nerve of the k -th member of an appropriate coarsening sequence for \mathcal{B}^0 . For each k , we have a canonical coarse equivalence

$$\mathcal{B}_k^0 \rightarrow \mathcal{B}^0$$

mapping $[0, 2i)$ to $\{0\}$ for $i \leq k - 1$. We need to show that the induced map

$$\varinjlim_k K_*^{lf}(\mathcal{B}_k^0, A) \rightarrow \varinjlim_k K_*(C^*(\mathcal{B}_k^0, A)) \cong K_*(C^*(\mathcal{B}^0, A))$$

is an isomorphism. Equivalently, we will prove that

$$\varinjlim_k K_*(D^*(\mathcal{B}_k^0, A)) = 0.$$

Let k be fixed and let us work with the adequate \mathcal{B}_k^0 -module of L^2 -function with values in the standard Hilbert A -module

$$H_A = l^2(\mathbb{N}) \otimes A.$$

For each $l > k$, we define a C^* -subalgebra

$$D^*(\mathcal{B}_k^0, A)_l \subset D^*(\mathcal{B}_k^0, A),$$

the closure of the set of all pseudolocal finite propagation operators that for $i \geq l$ do not interact between the two components of

$$\{0\} \cup [2i, \infty) \subset \mathcal{B}_k^0.$$

Note that this condition is weaker than restricting to operators of propagation less than $2l$ - this last condition does not define a subalgebra of $D^*(\mathcal{B}_k^0, A)$. Because K -theory commutes with direct limits,

$$K_*(D^*(\mathcal{B}_k^0, A)) = \varinjlim_l K_*(D^*(\mathcal{B}_k^0)_l, A).$$

The last K -theory groups can be calculated explicitly. Note the canonical decomposition

$$D^*(\mathcal{B}_k^0)_l = D^*(\Omega, A) \times \prod_{i \geq l} \mathbb{B}(H_A),$$

where

$$\Omega = \bigcup_{i=1, \dots, k-1} [0, \infty) \cup \bigcup_{i=k, \dots, l-1} (\{0\} \cup [2i, \infty)) \cup \bigcup_{i=l, l+1, \dots} [2i, \infty).$$

The algebra $\prod_{i \geq l} \mathbb{B}(H_A)$ is the multiplier algebra of $\prod_{i \geq l} \mathbb{K}(H_A)$ and therefore has vanishing K -theory, cf. [28]. The K -theory of the algebra $D^*(\Omega, A)$ appears in the long exact sequence

$$\dots \rightarrow K_*(C^*(\Omega, A)) \rightarrow K_*(D^*(\Omega, A)) \rightarrow K_*^{lf}(\Omega, A) \xrightarrow{\mu_\infty} K_{*-1}(C^*(\Omega, A)) \rightarrow \dots$$

and can therefore be studied by examining the coarse assembly map μ_∞ . Now Ω is coarsely equivalent to the flasque space $\bigcup_{i \in \mathbb{N}} [0, \infty)$ and hence

$$K_*(C^*(\Omega, A)) = 0.$$

On the other hand,

$$K_0^{lf}(\Omega, A) = \prod_{k \leq i \leq l-1} \mathbb{Z}, \quad K_1^{lf}(\Omega, A) = 0,$$

by the fact that the locally finite K -homology of a disjoint union is the direct product of the locally finite K -homologies of the individual components. Altogether, we have

$$K_1(D^*(\mathcal{B}_k^0, A)) = \lim_{\rightarrow l} K_1(D^*(\mathcal{B}_k^0, A)_l) = \bigoplus_{i \geq k} \mathbb{Z}$$

and $K_0(D^*(\mathcal{B}_k^0, A)) = 0$. We conclude

$$\lim_{\rightarrow k} K_1(D^*(\mathcal{B}_k^0, A)) = \lim_{\rightarrow k} \bigoplus_{i \geq k} \mathbb{Z} = 0$$

which finishes the proof of Proposition 5.2. □

For the proof of Theorem 1.7 in the next section we need a generalization of the construction underlying Lemma 5.14 in [22]. Let M be a complete connected Riemannian manifold of positive dimension with fundamental group π . We denote by \widetilde{M} the universal cover of M . The adequate $C_0(\widetilde{M})$ -module $L^2(\widetilde{M})$ carries an induced (right) unitary π -operation. As usual, let $C_\pi^*(\widetilde{M})$ be the C^* -algebra generated by locally compact π -invariant operators $L^2(\widetilde{M}) \rightarrow L^2(\widetilde{M})$ of finite propagation. We furthermore consider the adequate $C_0(M)$ -module $L^2(M, L)$, where

$$L = \widetilde{M} \times_\pi C_{\text{red}}^* \pi$$

is the Mishchenko line bundle on M (we equip \widetilde{M} and $C_{\text{red}}^* \pi$ with the canonical right respectively left π -actions). Note that $L^2(M, L)$ is a Hilbert- $C_{\text{red}}^* \pi$ -module in a canonical way. Denoting by $C^*(M, C_{\text{red}}^* \pi)$ the algebra generated by locally compact $C_{\text{red}}^* \pi$ -linear finite propagation operators $L^2(M, L) \rightarrow L^2(M, L)$ we wish to define a C^* -algebra map

$$\psi: C_\pi^*(\widetilde{M}) \rightarrow C^*(M, C_{\text{red}}^* \pi).$$

The construction of ψ is almost tautological. Let

$$T: L^2(\widetilde{M}) \rightarrow L^2(\widetilde{M})$$

be a π -invariant locally compact operator of propagation $R > 0$ and let $\sigma: M \rightarrow L$ be an L^2 -section of the Mishchenko line bundle. We can identify σ with a π -equivariant map

$$f: \widetilde{M} \rightarrow C_{\text{red}}^* \pi.$$

Here π acts on the right on $C_{\text{red}}^* \pi$ by $\xi \cdot \gamma := \gamma^{-1} \cdot \xi$. Let us assume for the moment that f has image contained in $\mathbb{C}[\pi] \subset C_{\text{red}}^* \pi$. This map can be considered as a π -labeled family of maps

$\widetilde{M} \longrightarrow \mathbb{C}$. To each of these maps, the operator T is applied. Because T is π -equivariant, the resulting map

$$T(f): \widetilde{M} \longrightarrow \mathbb{C}[\pi]$$

is again π -equivariant and hence induces a section of the bundle

$$\widetilde{M} \times_{\pi} \mathbb{C}[\pi] \longrightarrow M.$$

The construction for general f is by completion. By definition, the section of $L \longrightarrow M$ obtained in this way is equal to $\psi(T)(\sigma)$. By construction,

$$\psi(T): L^2(M, L) \longrightarrow L^2(M, L)$$

is locally compact and has propagation less or equal to R . (Notice that part of the propagation may go in the $C_{\text{red}}^* \pi$ -direction.) We emphasize that the map Ψ is not in general an isomorphism of C^* -algebras, because the propagation into the $C_{\text{red}}^* \pi$ direction is not required to be bounded in $C^*(M, C_{\text{red}}^* \pi)$.

REMARK 5.4. – Note that this construction also works if, instead of π , a subgroup H acts freely on \widetilde{M} , and we work with the Hilbert $C_{\text{red}}^* \pi$ -module bundle $\widetilde{M} \times_H C_{\text{red}}^* \pi$.

6. Proof of Theorem 1.7

By a suspension argument, we may restrict to the case of even n . For each $i \in \{1, 2, 3, \dots\}$, choose a connected cover

$$M_{1/i} \longrightarrow M$$

together with a $\frac{1}{i}$ -contracting map

$$f_{1/i}: M_{1/i} \longrightarrow S^n$$

which is constant (with value equal to the south pole $S \in S^n$) outside a compact subset of $M_{1/i}$ and which is of nonzero K -theoretic degree $z_i \in \mathbb{Z}$. The maps $f_{1/i}$ induce a coarse map

$$\phi: \mathcal{M} = \coprod_{i \in \mathbb{N}} M_{1/i} \longrightarrow \mathcal{B}^n.$$

Thanks to the whisker present in S^n , we simply map a point on the region outside the compact set, where $f_{1/i}$ is constant, to the point on the whisker whose distance to the origin is the distance to the compact set. Further, we set

$$\Gamma_i = \pi_1(M_{1/i})$$

with respect to an arbitrary basepoint and consider the adequate $M_{1/i}$ -module with coefficients in $C_{\text{red}}^* \Gamma_i$ defined by $L^2(M_{1/i}, L_i)$, the space of L^2 -sections of the Mishchenko line bundle

$$L_i = \widetilde{M} \times_{\Gamma_i} C_{\text{red}}^* \Gamma_i \longrightarrow M_{1/i}.$$

Recalling that $\widetilde{\mathcal{M}}$ is a disjoint union of copies of \widetilde{M} , we have a transfer map

$$\Delta: C^*(\widetilde{\mathcal{M}}) \longrightarrow C^*(\widetilde{\mathcal{M}})$$

induced by the diagonal embedding

$$\mathbb{B}(L^2(\widetilde{\mathcal{M}})) \longrightarrow \prod_i \mathbb{B}(L^2(\widetilde{M})) \subset \mathbb{B}(L^2(\widetilde{\mathcal{M}})).$$

This map restricts to a map between algebras of locally compact operators of finite propagation and hence induces the map Δ .

Let

$$\Gamma := \bigoplus_i \Gamma_i \subset \bigoplus_i \pi_1(M).$$

We define the Mishchenko bundle

$$\mathcal{L} := \prod_{i \in \mathbb{N}} \widetilde{M}_{1/i} \times_{\Gamma_i} C_{\text{red}}^* \Gamma \rightarrow \prod_i M_{1/i} = \mathcal{M}.$$

Our argument uses $C_{\text{red}}^* \Gamma$ as a coefficient C^* -algebra where we work with the adequate \mathcal{M} -module $L^2(\mathcal{M}, \mathcal{L})$. (Here we assume again that $\dim M > 0$ to make sure that this module is adequate.)

REMARK 6.1. – The heuristic meaning of this construction is that we would have to choose a coefficient C^* -algebra on \mathcal{M} that varies from component to component and is equal to $C_{\text{red}}^* \Gamma_i$ over $M_{1/i}$; we artificially blow this up to $C_{\text{red}}^* \Gamma$ to avoid the necessity to develop additional theory.

By performing the construction at the end of Section 5, in particular Remark 5.4, on each component of \mathcal{M} separately, we get a map of C^* -algebras

$$\psi: C_{\Gamma}^*(\widetilde{\mathcal{M}}) \longrightarrow C^*(\mathcal{M}; C_{\text{red}}^* \Gamma)$$

as follows. Fix an L^2 -section σ of the Mishchenko line bundle \mathcal{L} , which is a bundle of free Hilbert- $C_{\text{red}}^* \Gamma$ -modules of rank one over \mathcal{M} . The section σ is the direct sum of sections (σ_i) , where σ_i is the restriction to $\widetilde{M}_{1/i}$, a section of the restriction of L to the Mishchenko bundle over $M_{1/i}$. Moreover, Γ acts on $\widetilde{M}_{1/i}$ via the projection $\Gamma \rightarrow \Gamma_i$ with a free and discrete action of Γ_i . Consequently, Remark 5.4 applies and we can define $\psi(T)(\sigma)$ as the direct sum $\psi(T)(\sigma) := (\psi(T_i)(\sigma_i))_{i \in \mathbb{N}}$. With this definition $\psi(T)$ has propagation R , and this gives the required homomorphism of C^* -algebras

$$\psi: C_{\Gamma}^*(\widetilde{\mathcal{M}}) \longrightarrow C^*(\mathcal{M}; C_{\text{red}}^* \Gamma).$$

If X is a topological space and A a C^* -algebra, we define $K^{lf}(X; A) := KK(C_0(X), A)$.

The proof of Theorem 1.7 now proceeds via the following commutative diagram, where we set $\pi := \pi_1(M)$:

$$\begin{array}{ccccc} K_0(M) & \xrightarrow[\cong]{PD} & K_1(D_{\pi}^* \widetilde{M} / C_{\pi}^* \widetilde{M}) & \xrightarrow{\partial} & K_0(C_{\pi}^* \widetilde{M}) \xrightarrow{\cong} K_0(C_{\text{red}}^* \pi) \\ \downarrow tr & & \downarrow tr & & \downarrow tr \\ K_0^{lf}(\mathcal{M}) & \xrightarrow[\cong]{PD} & K_1(D_{\Gamma}^* \widetilde{\mathcal{M}} / C_{\Gamma}^* \widetilde{\mathcal{M}}) & \xrightarrow{\partial} & K_0(C_{\Gamma}^* \widetilde{\mathcal{M}}) \\ \downarrow [\mathcal{L}] \cap - & & & & \downarrow \psi \\ K_0^{lf}(\mathcal{M}, C_{\text{red}}^* \Gamma) & \longrightarrow & KX_0(\mathcal{M}, C_{\text{red}}^* \Gamma) & \xrightarrow{\mu_{\infty}} & K_0(C^*(\mathcal{M}, C_{\text{red}}^* \Gamma)) \\ \downarrow \phi_* & & \downarrow \phi_* & & \downarrow \phi_* \\ K_0^{lf}(\mathcal{B}^n, C_{\text{red}}^* \Gamma) & \xrightarrow{cX} & KX_0(\mathcal{B}^n, C_{\text{red}}^* \Gamma) & \xrightarrow[\cong]{\mu_{\infty}} & K_0(C^*(\mathcal{B}^n, C_{\text{red}}^* \Gamma)). \end{array}$$

The horizontal arrows denoted PD are Paschke duality isomorphism, compare e.g. [23, Section 3] and [18]. The vertical maps tr are transfer maps, on the level of C^* and D^* they are simply given by diagonal embedding. The map ∂ is a boundary map in a long exact K -theory sequence, the compositions of tr and ∂ are Baum–Connes assembly maps μ (compare [23] again). Finally, cX is the coarsening map from locally finite to coarse K -homology.

In order to detect the nonvanishing of $\alpha(M)$ claimed by Theorem 1.7, we chase the K -theoretic fundamental class $[M]_K \in K_0(M)$ through this diagram. Because the coarse assembly map μ_∞ is an isomorphism for the space \mathcal{B}^n by Proposition 5.2, we only need to show that the image of $[M]_K$ under the map

$$\omega = cX \circ \phi_* \circ ([\mathcal{L}] \cap -) \circ tr : K_0(M) \longrightarrow KX_0(\mathcal{B}^n; C_{\text{red}}^*\Gamma)$$

is non-zero. This will ultimately follow from a form of Atiyah’s L^2 -index theorem.

For a metric space X and a C^* -algebra A , we define the K -homology with compact supports and coefficients in A as

$$KKR(X; A) := \lim_{Q \subset X} KK(C_0(Q); A),$$

where the limit goes over the set of compact subsets of X ordered by inclusion. Note in particular that $KKR(X; \mathbb{C}) = K_0(X)$, if X is homotopy equivalent to a CW -complex. The canonical inclusions $\mathbb{C} \rightarrow C_0(Q)$ induce an augmentation map

$$\epsilon : KKR(X; A) \rightarrow KK(\mathbb{C}; A).$$

Now let $E \rightarrow S^n$ be a finite dimensional unitary bundle so that (with $k := \dim E$) the virtual bundle $E - \underline{\mathbb{C}}^k$ represents a generator of $K^0(S^n, S)$ compatible with the orientation used for defining the K -theoretic degrees z_i at the beginning of this section. (Recall that n is even by assumption.) We define a map

$$KK(C_0(\mathcal{B}^n); C_{\text{red}}^*\Gamma) = \prod_i KK(C_0(\underline{S}^n(i)); C_{\text{red}}^*\Gamma) \longrightarrow \prod_i K_0(C_{\text{red}}^*\Gamma) \longrightarrow \prod_i \mathbb{R}$$

where each component of the last map is the composition

$$KK(C_0(\underline{S}^n); C_{\text{red}}^*H) \xrightarrow{-\cap[E - \underline{\mathbb{C}}^k]} KKR(\underline{S}^n; C_{\text{red}}^*\Gamma) \xrightarrow{\epsilon} KK(\mathbb{C}; C_{\text{red}}^*\Gamma) \xrightarrow{\tau} \mathbb{R}.$$

Here, the first map is given by the cap product with the K -cohomology class with compact support represented by the virtual bundle $[E - \underline{\mathbb{C}}^k]$. The last map is induced by the canonical trace $\tau : C_{\text{red}}^*\Gamma \rightarrow \mathbb{C}$.

LEMMA 6.2. – *The composition*

$$K_0^{lf}(\mathcal{B}^n; C_{\text{red}}^*\Gamma) \longrightarrow \prod_i K_0(C_{\text{red}}^*\Gamma) \longrightarrow \prod_i \mathbb{R} \longrightarrow (\prod_i \mathbb{R}) / (\bigoplus_i \mathbb{R})$$

factors through the canonical map

$$K_0^{lf}(\mathcal{B}^n; C_{\text{red}}^*\Gamma) \longrightarrow KX_0(\mathcal{B}^n; C_{\text{red}}^*\Gamma).$$

This is an immediate consequence of the calculation appearing in the proof of Proposition 5.2.

The following proposition concludes the proof that $\alpha(M) \neq 0$.

PROPOSITION 6.3. – *The composition*

$$K_0(M) \xrightarrow{\omega} KX_0(\mathcal{B}^n; C_{\text{red}}^*\Gamma) \longrightarrow \left(\prod_i \mathbb{R} \right) / \left(\bigoplus_i \mathbb{R} \right)$$

sends the K -theoretic fundamental class of M to the element represented by the sequence (z_1, z_2, \dots) .

Recall that $z_i \in \mathbb{Z}$ is defined as the K -theoretic degree of the map

$$f_{1/i}: M_{1/i} \longrightarrow S^n$$

and non-zero by assumption. Hence, the sequence given in Proposition 6.3 represents a non-zero class in the quotient $(\prod \mathbb{R}) / (\bigoplus \mathbb{R})$ and the proof of Theorem 1.7 is complete modulo the proof of Proposition 6.3.

To prove this proposition, we first need to recall a form of Atiyah's L^2 -index theorem. Let Γ be an arbitrary (countable) discrete group. We consider the composition

$$K_*(B\Gamma) \xrightarrow{\mu} K_*(C_{\text{red}}^*\Gamma) \xrightarrow{\tau} \mathbb{R},$$

where the first map is the Baum–Connes assembly map and the second map is induced by the canonical trace $\tau: C_{\text{red}}^*\Gamma \rightarrow \mathbb{C}$. Now the homological form of the L^2 -index theorem reads as follows. The elegant proof in [5] applies without change.

PROPOSITION 6.4. – *The composition $\tau_* \circ \mu$ is equal to the map*

$$K_*(B\Gamma) \longrightarrow K_*(\text{pt.}) \cong \mathbb{Z} \hookrightarrow \mathbb{R},$$

induced by mapping $B\Gamma$ to a point (recall that $K_*(B\Gamma)$ denotes K -homology with compact support). Of course, given a (not necessarily compact) manifold X and a map $c: X \rightarrow B\Gamma$, $\tau_* \circ \mu \circ c_*: K_*(X) \rightarrow K_*(\mathbb{C})$ is then equal to the map induced by the projection $X \rightarrow \text{pt.}$

Proof of Proposition 6.3. – It is enough to show that under the composition

$$K_0(M) \longrightarrow KK(C_0(\mathcal{B}^n); C_{\text{red}}^*\Gamma) \longrightarrow \prod_i K_0(C_{\text{red}}^*\Gamma) \longrightarrow \prod_i \mathbb{R}$$

the fundamental class is sent to the sequence (z_1, z_2, z_3, \dots) . This will follow from the fact that the composition

$$\begin{aligned} K_0(M) &\longrightarrow KK(C_0(M_{1/i}); C_{\text{red}}^*\Gamma) \\ &\xrightarrow{(f_{1/i})_*} KK(C_0(\underline{S}^n); C_{\text{red}}^*\Gamma) \\ &\xrightarrow{-\cap[E-\underline{\mathbb{C}}^k]} KK(R(\underline{S}^n); C_{\text{red}}^*\Gamma) \\ &\xrightarrow{\epsilon} KK(\mathbb{C}; C_{\text{red}}^*\Gamma) \xrightarrow{\tau} \mathbb{R} \end{aligned}$$

sends the K -theoretic fundamental class to z_i (the first map is a composition of the transfer map and the slant product with the Mishchenko bundle).

First we observe that the preceding composition is equal to the composition

$$\begin{aligned} K_0(M) &\xrightarrow{tr} K_0^{lf}(M_{1/i}) = KK(C_0(M_{1/i}); \mathbb{C}) \\ &\xrightarrow{-\cap f_{1/i}^*([E-\mathbb{C}^k])} K_0(M_{1/i}) \\ &\xrightarrow{-\cap [L]} KK R(M_{1/i}; C_{red}^* \Gamma) \\ &\xrightarrow{\epsilon} KK(\mathbb{C}; C_{red}^* \Gamma) \xrightarrow{\tau} \mathbb{R}. \end{aligned}$$

Now the composition

$$K_0(M_{1/i}) \xrightarrow{-\cap [L]} KK R(M_{1/i}; C_{red}^* \Gamma) \xrightarrow{\epsilon} KK R(\mathbb{C}; C_{red}^* \Gamma) = K_0(C_{red}^* \Gamma_i)$$

is (by one possible definition of μ) equal to the composition

$$K_0(M_{1/i}) \xrightarrow{c_*} K_0(B\Gamma) \xrightarrow{\mu} K_0(C_{red}^* \Gamma).$$

Here c is the composition

$$c: M_i \longrightarrow B\Gamma_i \rightarrow B\Gamma$$

where the first map classifies the universal cover of M_i and the second is induced from the canonical inclusion.

Therefore, using Proposition 6.4, we need to show that the composition

$$\begin{array}{ccccc} K_0(M) & \xrightarrow{tr} & K_0^{lf}(M_{1/i}) & \xrightarrow{-\cap f_{1/i}^*([E-\mathbb{C}^k])} & K_0(M_{1/i}) & \xrightarrow{\epsilon} & K_0(\text{pt.}) = \mathbb{Z} \\ & & \downarrow (f_{1/i})_* & & \downarrow (f_{1/i})_* & & \downarrow = \\ & & K_0(S^n, S) & \xrightarrow{\cap [E-\mathbb{C}^k]} & K_0(S^n) & \xrightarrow{\epsilon} & K_0(\text{pt.}) \end{array}$$

sends the K -theoretic fundamental class of M to z_i . But this assertion is immediate. \square
